Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

Field of the Invention

[0001] The invention relates to a method of inspecting a printed paper on which images are printed repeatedly. In particular, the invention relates to the method which is useful for inspection of stained parts and blurred parts and inspection of shortage or excess of printed density.

Prior Art

[0002] The document JP 04 299 147 A discloses a method for inspecting the quality of printed matters without using sample data and for making a detection of abnormalities in a printing machine according to the results of the inspection. The conventional method comprises the steps of reading multi valued data of reference of each of colors from a printed paper on which images are printed to be good, wherein the multi level data of reference are converted into two level data of reference so that two level images of reference can be reproduced in a memory from the two level data of reference. Further, the step of reading multi level data of inspection of each of the colors from a printed paper which is fed when expecting is known from this prior art document. The multi level data of inspection are converted into two level data of inspection so that two level images of inspection can be reproduced in the memory from the two level data of inspection. Finally, the step of comparing the two level images of inspection with the two level images of reference for inspection of stained parts and blurred parts is performed in the conventional method.

[0003] The document EP-A-0 194 331 discloses an inspecting device and method for detecting a defect occurred on a printed sheet by comparing the state of the printed sheet during printing with a reference state in a printing machine.

[0004] The document EP-A-0 795 400 discloses a device and method for automatically aligning a production copy image with a reference copy image in a printing press control system.

[0005] Regarding a printed paper such as a news paper on which images are printed repeatedly by a printing press, an apparatus is generally combined with the printing press to inspect the printed paper. The apparatus should be useful for inspection of stained parts and blurred parts and inspection of shortage or excess of printed density. In this connection, the apparatus has heretofore been arranged to read multi level data of reference of each of colors from a printed paper on which images are printed to be good, and read multi level data of inspection of each of colors from a printed paper which is fed when inspecting. In addition, it has been conventional to compare the multi level data of inspection with the multi level data of reference at every pixel for inspection of stained parts and blurred parts. It has also been usual to compare the multi level data of inspection with

the multi level data of reference at every pixel for inspection of shortage or excess of printed density.

[0006] However, this way must take a considerable time for inspection of stained parts and blurred parts and inspection of shortage or excess of printed density, to be low in efficiency. Furthermore, it is difficult to make a distinction between the inspection of stained parts or blurred parts and the inspection of shortage or excess of printed density when executing the inspections simultaneously by reason that each of the inspections is dependent on the comparison of the multi level data of inspection with the multi level data of reference.

[0007] By the way, Japanese Laid-Open Patent Publication No. 270,939 of 1991 discloses a method of inspecting a printed product, which calculates the number of dots corresponding to the pixels of print to find out the defects of print. Japanese Laid-Open Patent Publication No. 299,147 of 1992 discloses an apparatus for inspecting a printed product, in which two level images are converted into distance images to determine if good or no good. Japanese Laid-Open Patent Publication No. 121,721 of 1995 discloses a method of inspecting a printed product, which compares the number of islands and the value of area with data of reference to appreciate the quality of print.

[0008] It is therefore an object of the invention to provide a method of inspecting a printed paper on which images are printed repeatedly, the method and the apparatus overcoming the above problems.

[0009] Other object of the invention is to provide the method which is useful for inspection of stained parts and blurred parts and inspection of shortage or excess of printed density, to be high in efficiency without taking time.

[0010] Other object of the invention is to provide the method which can make a distinction between the inspection of stained parts or blurred parts and the inspection of shortage or excess of printed density without difficulty.

Summary of the Invention

[0011] According to the invention, the method comprises the steps according to claim 1.

Brief Description of the Drawings

[0012]

Fig. 1 is a block diagram of a preferred embodiment of the invention.

Fig. 2 is an explanatory view of multi level data converted into two level data in the apparatus of Fig. 1.

Fig. 3 is an explanatory view of images printed to be good on a printed paper for establishing a reference for inspection of stained parts and blurred parts.

Fig. 4 is an explanatory view of two level images of reference at the threshold of lowest stained density.

Detailed Description of the Preferred Embodiments

[0013] Turning now to the drawings, Fig. 1 illustrates an apparatus for inspecting a printed paper such as a news paper on which images are printed repeatedly by a printing press, according to the invention. The apparatus includes red, blue and green light sources or a white light source 2 by which the printed paper is illuminated. The apparatus further includes data reading means 4 for reading multi level data of reference of each of colors from a printed paper on which images are printed to be good, and reading multi level data of each of colors from a printed paper which is fed when inspecting.

[0014] A signal generator 6 generates timing and clock signals in response to a detecting signal fed from a rotary encoder 8 detecting the rotation of printing press. The timing and clock signals are fed to a selector 10, an operational amplifier 12, an A/D converter 14, a shading corrector 16 and a memory and data transferring part 18. The multi level data of reference and the multi level data of inspection are fed from the data reading means 4, taken selectively by the selector 10, amplified by the operational amplifier 12, converted into digital codes by the A/D converter 14, standard white levels corrected by the shading corrector 16 and stored in the memory and data transferring part 18.

[0015] The apparatus further includes a processor 20, data processing means 22, a memory 24 and comparing means 26. The processor 20 comprises a CPU for controlling the whole apparatus by executing a software for performance of function of the data processing means 22, the memory 24 and the comparing means 26. Fur-

thermore, the timing and clock signals are fed to the data processing means 22 by which the multi level data of reference are converted into two level data of reference so that two level images of reference can be reproduced in the memory 24 from the two level data of reference. In addition, the multi level data of inspection are converted into two level data of inspection by the data processing means 22. Two level images of inspection are reproduced in the memory 24 from the two level data of inspection.

[0016] The comparing means 26 compares the two level images of inspection with the two level images of reference for inspection of stained parts and blurred parts. In the embodiment, the comparing means 26 including predetermining means for predetermining areas for decision of stained parts or blurred parts. The comparing means 26 further including deciding means for deciding on stained parts or blurred parts when the two level images of inspection include portions disagreeing with the two level images of reference and the portions have areas exceeding the areas for decision of stained parts or blurred parts.

[0017] As to the multi level data of reference and the multi level data of inspection converted into the two level data of reference and the two level data of inspection, the data processing means 22 includes predetermining means for predetermining a threshold (a) of lowest stained density near a level (L1) of lowest printed density for inspection of stained parts and predetermining a threshold (b) of highest blurred density near a level (L2) of highest printed density for inspection of blurred parts, as shown in Fig. 2. The threshold (a) of lowest stained density is disposed above the level (L1) of lowest printed density. The threshold (b) of highest blurred density is disposed below the level (L2) of highest printed density. The multi level data of reference and the multi level data of inspection are converted into the two level data of reference and the two level data of inspection by using the thresholds (a) and (b) of lowest stained density and highest blurred density. In the embodiment, the multi level data of reference and the multi level data of inspection are converted into the two level data of reference and the two level data of inspection when exceeding the threshold (a) or (b).

[0018] For example, Fig. 3 illustrates the images printed to be good on a printed paper for establishing a reference for inspection of stained parts and blurred parts. Fig. 4 illustrates the two level data of reference at the threshold (a) of lowest stained density. Fig. 5 illustrates the two level data of reference at the threshold (b) of highest blurred density. On the other hand, Fig. 6 illustrates the images printed for inspection and including stained parts and blurred parts. In this case, two level images of inspection are obtained to include stained parts at the threshold (a) of lowest stained density, as shown in Fig. 7. Furthermore, two level images of inspection are obtained to include blurred parts at the threshold (b) of highest blurred density, as shown in Fig. 8. It should

therefore be understood that the apparatus compares the two level images of Fig. 7 with the two level images of Fig. 4 to recognize that the two level images of Fig. 7 includes portions disagreeing with the two level images of Fig. 4. Furthermore, the apparatus compares the two level images of Fig. 8 with the two level images of Fig. 6 to recognize that the two level images of Fig. 8 includes portions disagreeing with the two level images of Fig. 5. The apparatus then decides on stained parts or blurred parts when the portions have areas exceeding the areas for decision of stained parts or blurred parts.

[0019] In the embodiment, the data processing means 22 further includes predetermining means for predetermining a limit (c) of minus of differential density independently of the threshold (a) of lowest stained density for inspection of shortage of printed density and predetermining a limit (d) of plus of differential density independently of the threshold (b) of highest blurred density for inspection of excess of printed density. The limit (c) of minus of differential density is disposed above the threshold (a) of lowest stained density. The limit (d) of plus of differential density is disposed below the threshold (b) of highest blurred density. The comparing means 26 further includes predetermining means for predetermining areas for decision of shortage or excess of printed density. In addition, the comparing means 26 is arranged to compare the multi level data of inspection with the multi level data of reference at every pixel for recognition of difference between the multi level data of reference and the multi level data of inspection. The comparing means 26 further includes deciding means for deciding on shortage or excess of printed density when the difference exceeds the limit (c) or (d) of minus of differential density or plus of differential density by portions having areas which exceed the areas for decision of shortage or excess of printed density.

[0020] In this connection, Fig. 9 illustrates the images printed to be good on the printed paper for establishing a reference for inspection of shortage or excess of printed density. Fig. 10 illustrates multi level images of inspection at the limit (c) of minus of differential density. Fig. 11 illustrates multi level images of inspection at the limit (d) of plus of differential density.

[0021] It should therefore be recognized that the apparatus includes predetermining means for predetermining a limit (a) of lowest stained density near a level (L1) of lowest printed density for inspection of stained parts and predetermining a limit (b) of highest blurred density near the level (L2) of highest printed density for inspection of blurred parts. The limit (a) of lowest stained density is disposed above the level (L1) of lowest printed density. The limit (b) of highest blurred density is disposed below the level (L2) of highest printed density. The apparatus further includes predetermining means for predetermining the limit (c) of minus of differential density independently of the limit (a) of lowest stained density for inspection of shortage of printed density and predetermining the limit (d) of plus of differential density independently

of the limit (b) of highest blurred density for inspection of excess of printed density. The limit (c) of minus of differential density is disposed above the limit (a) of lowest stained density. The limit (d) of plus of differential density is disposed below the limit (b) of highest blurred density. The apparatus is arranged to use the multi level data of reference, the multi level data of inspection, the limit (a) of lowest stained density and the limit (b) of highest blurred density for inspection of stained parts and blurred parts. The apparatus is further arranged to use the multi level data of reference, the multi level data of inspection, the limit (c) of minus of differential density and the limit (d) of plus of differential density for inspection of shortage or excess of printed density.

[0022] It should also be recognized that in the embodiment, the limit (a) of lowest stained density comprises the threshold of lowest stained density. The limit (b) of highest blurred density comprises the threshold of highest blurred density. In addition, the multi level data of reference are converted into the two level data of reference when exceeding the threshold (a) or (b) of lowest stained density or highest blurred density. The multi level data of inspection are converted into the two level data of inspection when exceeding the threshold (a) or (b) of lowest stained density or highest blurred density, as described above. Furthermore, the two level images of reference and inspection are reproduced in the memory from the two level data of reference and inspection, to compare the two level images of inspection with the two level images of reference for inspection of stained parts or blurred parts, as also described above.

[0023] Accordingly, unlike the prior art, the apparatus is not required to compare the multi level data of inspection with the multi level data of reference at every pixel for inspection of stained parts and blurred parts. The apparatus is merely required to compare the two level images of inspection with the two level images of reference for inspection of stained parts and blurred parts. The apparatus is therefore useful for inspection of stained parts and blurred parts and inspection of shortage or excess of printed density, to be high in efficiency without taking time.

[0024] Furthermore, the apparatus is arranged to use the limits or thresholds (a) and (b) for inspection of stained parts and blurred parts, and use the limits (c) and (d) independent of the limits (a) and (b) for inspection of shortage or excess of printed density. In addition, the inspection of stained parts and blurred parts is dependent on the comparison of the two level images of inspection with the two level images of reference. The inspection of shortage or excess of printed density is dependent on the comparison of the multi level data of inspection with the multi level data of reference. The apparatus can therefore make a distinction between the inspection of stained parts or blurred parts and the inspection of shortage or excess of printed density without difficulty.

[0025] Furthermore, in the embodiment, the comparing means 26 is arranged to partition the two level images

of reference and the two level images of inspection into parts (1) to (8), as shown in Fig. 12, to compare the two level images of inspection with the two level images of reference at every part. The two level images of reference and the two level images of inspection are stored in the memory 24 at every part for comparison of them with each other at every pixel. This arrangement can save time for storage and comparison of the two level images and decision of stained parts or blurred parts, to improve efficiency.

[0026] In this connection, it is preferable to predetermine the area of each of the parts (1) to (8) to effectively save the time for storage, comparison and decision. It should be understood that the time is lengthen in proportion to the increase of the area. The parts (1) to (8) can be stored at positions, with sizes and in a sequence which are selected by executing the soft ware for controlling. The parts (1) to (8) may include specific small ones with increased number to partially speed up the decision.

[0027] The apparatus further includes a transmission part 28 for transmitting information to a system control part 30 from the comparing and deciding means 12. The information includes the decision of stained parts or blurred parts and the decision of shortage or excess of printed density. The information further includes the page, position, size and degree of stained parts or blurred parts and shortage or excess of printed density. The information further includes control data of apparatus. The system control part 30 transmits a command for start, end and emergency stop of inspection to a press control part 32 in response to the control data.

[0028] The system control part 30 includes alarm means for generating an alarm of stained parts or blurred parts when finding out the stained parts or blurred parts. The system control part 30 further includes alarm means for generating an alarm of shortage or excess of printed density when finding out the shortage or excess of printed density.

[0029] In addition, the system control part 30 includes a screen for indicating information about the display of pages printed by the printing press. The screen is changed to indicate the page, position, size and degree of stained parts or blurred part and shortage or excess of printed density when finding out. The system control part 30 is arranged to predetermine parameters of inspection when waiting.

[0030] The press control part 32 has a function of control of printing press and transmits information to the inspection apparatus when waiting. The information includes the display of pages and positions to be printed and the number of printing plate.

[0031] Furthermore, the apparatus may be arranged to detect the positional variations of the printed paper at every page when the printed paper is fed, to compensate the two level images reproduced in the memory for the positional variations.

[0032] In the embodiment, the apparatus generates a start signal for start of inspection, as shown in Fig. 13.

The apparatus then reads multi level data of reference of each of colors from a printed paper and partition the multi level data of reference into $1/n$ parts of 1 page when an operator judges that images are printed on the printed paper to be good so that the multi level data of reference can be stored at every $1/n$ part in the memory (S 1). The multi level data of reference are converted into two level data of reference by using the thresholds (a) and (b) of Fig. 2 so that the two level images of reference can be reproduced at every $1/n$ part in the memory (S 2). Printed papers are then fed successively for inspection. The apparatus reads multi level data of inspection of each of colors from the printed paper and partition the multi level data of inspection into $1/n$ parts of 1 page. The multi level data of inspection are stored at every $1/n$ part in the memory and converted into two level data of inspection by using the thresholds (a) and (b) so that the two level images of inspection can be reproduced at every $1/n$ part in the memory (S 3) for comparison of two level images and comparison of multi level data.

[0033] As to the comparison of two level images, the apparatus extracts the two level images of reference of No. $1/n$ part relating to the threshold (a) from the memory (S 5) and the two level images of inspection of No. $1/n$ part relating to the threshold (a) from the memory (S 6) to compare them with each other (S 7), as shown in Fig. 14. The apparatus then recognizes whether the two level images of inspection include portions disagreeing with the two level images of reference or not and recognizes where the portions are positioned and what areas the portions have so that the positions and areas of disagreeing portions can be stored in the memory (S 8). The same steps are accomplished repeatedly at every $1/n$ part toward the two level images of reference and inspection of No. n/n part (S 9 to S 12). The apparatus then collects the results of inspection (S 13) to determine whether the positions and areas of disagreeing portions are present or not (S 14) and makes a change to the next inspection when being not present. The apparatus further determines whether the collecting areas of disagreeing portions exceed the predetermined areas or not (S 15) and make a change to the next inspection when not exceeding. The apparatus generates an alarm of stained parts when exceeding (S 16).

[0034] Furthermore, the apparatus extracts the two level images of reference of No. $1/n$ part relating to the threshold (b) from the memory (S 17) and the two level images of inspection of No. $1/n$ part relating to the threshold (b) from the memory (S 18) to compare them with each other (S 19). The apparatus then recognizes whether the two level images of inspection include portions disagreeing with the two level images of reference or not and recognizes where the portions are positioned and what areas the portions have so that the positions and areas of disagreeing portions can be stored in the memory (S 20). The same steps are accomplished repeatedly at every $1/n$ part toward the two level images of reference and inspection of No. n/n part (S 21 to S 24). The appa-

ratus then collects the results of inspection (S 25) to determine whether the positions and areas of disagreeing portions are present or not (S 26) and makes a change to the next inspection when being not present. The apparatus further determines whether the collecting areas of disagreeing portions exceed the predetermined areas or not (S 27) and make a change to the next inspection when not exceeding. The apparatus generates an alarm of blurred parts when exceeding (S 28).

[0035] It should be understood that what is meant by the positions of disagreeing portions in the steps (S 8 and S 20) is X and Y coordinate values of disagreeing pixels. The areas comprise the collection of adjacent disagreeing pixels, that is, X1 to Xn and Y1 to Yn pixels. These indicate the positions and sizes of stained parts in the case of threshold (a) and the positions and sizes of blurred parts in the case of threshold (b). The apparatus is arranged to predetermine the sizes (number of pixels) for generating the alarm only when exceeding the sizes. In addition, the apparatus is arranged to indicate the positions and sizes of stained or blurred parts in the 1/n to n/n parts of page when generating the alarm.

[0036] As to the comparison of multi level data, the apparatus extracts the multi level data of reference of No. 1/n part from the memory (S 30) and the multi level data of inspection of No. 1/n part from the memory (S 31) to compare them with each other at every pixel for recognition of difference between the multi level data of reference and the multi level data of inspection so that the positions and areas of difference can be stored in the memory (S 32), as shown in Fig. 15. The same steps are accomplished repeatedly at every 1/n part toward the multi level data of reference and inspection of No. n/n part (S 33 to S 35). The apparatus then collects the results of inspection (S 36) to determine whether the positions and areas of difference are present or not (S 37) and make a change to the next inspection when being not present. The apparatus further determines whether the collecting areas of difference exceed the predetermined areas or not (S 38) and make a change to the next inspection when not exceeding. The apparatus further determine whether the difference is plus or minus (S 39) to generate an alarm of excess of printed density when being plus (S 40) and generate an alarm of shortage of printed density when being minus (S 41).

[0037] It is preferable to generate the alarms of excess and shortage of printed density by marks different from each other, to indicate the marks alternatively when finding out the excess and shortage of printed density on the same page.

[0038] The apparatus compares the two level data and the multi level data repeatedly up to the end of printing.

[0039] The features of the description, the claims and the drawings, single or in any combination, are patentable and claimed herewith, as far as not excluded by the prior art. Each claim can depend on any one or more of the other claims.

Claims

1. A method of inspecting a printed paper on which images are printed repeatedly, the method comprising the steps of:

- predetermining a threshold (a) of lowest stained density near a level (L1) of lowest printed density for inspection of stained parts;
- predetermining a threshold (b) of highest blurred density near a level (L2) of highest printed density for inspection of blurred parts;
- reading multi valued data of reference of each of colors from a printed paper, the multi valued data of reference being converted into monochrome data of reference by using the thresholds (a, b) of lowest stained density and highest blurred density so that monochrome images of reference can be stored in a memory (24) from the monochrome data of reference;
- reading multi valued data of inspection of each of colors from a printed paper which is fed when inspecting, the multi valued data of inspection being converted into monochrome data of inspection by using the thresholds (a, b) of lowest stained density and highest blurred density so that monochrome images of inspection can be stored in the memory (24) from the monochrome data of inspection;
- comparing the monochrome images of inspection with the monochrome images of reference for inspection of stained parts and blurred parts;
- predetermining area for decision of stained parts or blurred parts;
- recognizing whether the monochrome images of inspection include portions disagreeing with the monochrome images of reference or not, where the portions are positioned and what areas the portions have, and deciding on stained parts or blurred parts when the portions have areas exceeding the areas for decision of stained parts or blurred parts;
- predetermining a limit (c) of minus of differential density independently of the threshold (a) of lowest stained density for inspection of shortage of printed density at every pixel;
- predetermining a limit (d) of plus of differential density independently of the threshold (b) of highest blurred density for inspection of excess of printed density at every pixel;
- comparing the multi valued data of inspection with the multi valued data of reference at every pixel for recognition of difference between the multi valued data of reference and the multi valued data of inspection;
- predetermining area for decision of shortage or excess of printed density;
- deciding on shortage or excess of printed density.

sity when the difference exceeds the limit (c, d) of minus of differential density or plus of differential density by portions having areas which exceed the areas for decision of shortage or excess of printed density; and

- executing the inspection and decision of stained parts and blurred parts and the inspection and decision of shortage and excess of printed density simultaneously.

2. The method as set forth in claim 1, wherein the step of comparing includes the step of partitioning the monochrome images of reference and the monochrome images of inspection into parts to compare the monochrome images of inspection with the monochrome images of reference at every part.
3. The method as set forth in claim 1 or 2, further comprising the step of generating an alarm of stained parts or blurred parts when finding out the stained parts or blurred parts.
4. The method as set forth in one of the claims 1 to 3, further comprising the step of detecting the positional variations of the printed paper at every page when the printed paper is fed, to compensate the monochrome images stored in the memory (24) for the positional variations.
5. The method as set forth in one of the claims 1 to 4, further comprising the step of generating an alarm of shortage or excess of printed density when finding out the shortage or excess of printed density.

Patentansprüche

1. Verfahren zur Überprüfung eines bedruckten Papiers, worauf wiederholt Bilder gedruckt werden, wobei das Verfahren die folgenden Schritte umfaßt:
 - Vorbestimmen einer Schwelle (a) der niedrigsten verschmutzten Dichte in der Nähe eines Niveaus (L1) der niedrigsten Druckdichte zur Überprüfung verschmutzter Teile;
 - Vorbestimmen einer Schwelle (b) der höchsten verschmierten Dichte in der Nähe eines Niveaus (L2) der höchsten Druckdichte zur Überprüfung verschmierter Teile;
 - Lesen mehrwertiger Referenzdaten jeder der Farben aus einem bedruckten Papier, wobei die mehrwertigen Referenzdaten durch Verwendung der Schwellen (a, b) der niedrigsten verschmutzten Dichte und der höchsten verschmierten Dichte in Monochrom-Referenzdaten umgesetzt werden, so daß Monochrom-Referenzbilder aus dem Monochrom-Referenzdaten in einem Speicher (24) gespeichert werden

können;

- Lesen mehrwertiger Überprüfungsdaten jeder der Farben aus einem bedruckten Papier, das bei der Überprüfung zugeführt wird, wobei die mehrwertigen Überprüfungsdaten durch Verwendung der Schwellen (a, b) der niedrigsten verschmutzten Dichte und der höchsten verschmierten Dichte in Monochrom-Überprüfungsdaten umgesetzt werden, so daß Monochrom-Überprüfungsbilder aus dem Monochrom-Überprüfungsdaten in dem Speicher (24) gespeichert werden können;

- Vergleichen der Monochrom-Überprüfungsbilder mit den Monochrom-Referenzbildern zur Überprüfung von verschmutzten Teilen und verschmierten Teilen;

- Vorbestimmen des Flächeninhalts für die Entscheidung über verschmutzte Teile oder verschmierte Teile;

- Erkennen, ob die Monochrom-Überprüfungsbilder Teile enthalten, die sich von den Monochrom-Referenzbildern unterscheiden, oder nicht, wo die Teile positioniert sind und welche Flächeninhalte die Teile aufweisen, und Entscheiden über verschmutzte Teile oder verschmierte Teile, wenn die Teile Flächeninhalte aufweisen, die die Flächeninhalte für die Entscheidung über verschmutzte Teile oder verschmierte Teile übersteigen;

- Vorbestimmen einer Grenze (c) von minus der Differenzdichte unabhängig von der Schwelle (a) der niedrigsten verschmutzten Dichte zur Überprüfung von zu wenig Druckdichte an jedem Pixel;

- Vorbestimmen einer Grenze (d) von plus der Differenzdichte unabhängig von der Schwelle (b) der höchsten verschmierten Dichte zur Überprüfung von zu viel Druckdichte an jedem Pixel;

- Vergleichen der mehrwertigen Überprüfungsdaten mit den mehrwertigen Referenzdaten an jedem Pixel zur Erkennung eines Unterschieds zwischen den mehrwertigen Referenzdaten und den mehrwertigen Überprüfungsdaten;

- Vorbestimmen eines Flächeninhalts für die Entscheidung über zu wenig oder zu viel Druckdichte;

- Entscheiden über zu wenig oder zu viel Druckdichte, wenn der Unterschied die Grenze (c, d) von minus der Differenzdichte oder plus der Differenzdichte um Teile mit Flächeninhalten, die die Flächeninhalte für die Entscheidung über zu wenig oder zu viel Druckdichte übersteigen, übersteigt; und

- gleichzeitiges Ausführen der Überprüfung und Entscheidung über verschmutzte Teile und verschmierte Teile und der Überprüfung und Entscheidung über zu wenig und zu viel Druckdichte.

2. Verfahren nach Anspruch 1, wobei der Schritt des Vergleichens den Schritt des Aufteilens der Monochrom-Referenzbilder und der Monochrom-Überprüfungsbilder in Teile umfaßt, um die Monochrom-Überprüfungsbilder an jedem Teil mit den Monochrom-Referenzbildern zu vergleichen. 5
3. Verfahren nach Anspruch 1 oder 2, ferner mit dem Schritt des Erzeugens eines Alarms über verschmutzte Teile oder verschmierte Teile, wenn die verschmutzten Teile oder verschmierten Teile herausgefunden werden. 10
4. Verfahren nach einem der Ansprüche 1 bis 3, ferner mit dem Schritt des Erkennens der Positionsschwankungen des bedruckten Papiers an jeder Seite, wenn das bedruckte Papier zugeführt wird, um die in dem Speicher (24) gespeicherten Monochrom-Bilder in bezug auf die Positionsschwankungen zu kompensieren. 15 20
5. Verfahren nach einem der Ansprüche 1 bis 4, ferner mit dem Schritt des Erzeugens eines Alarms über zu wenig oder zu viel Druckdichte, wenn zu wenig oder zu viel Druckdichte herausgefunden werden. 25

Revendications

1. Procédé d'examen d'un papier imprimé sur lequel des images sont imprimées de manière répétée, le procédé comprenant les étapes consistant à : 30
 - prédéterminer un seuil (a) de densité tachée la plus faible près d'un niveau (L1) de densité imprimée la plus faible en vue de l'examen de parties tachées, 35
 - prédéterminer un seuil (b) de densité de flou la plus haute près d'un niveau (L2) de densité imprimée la plus haute en vue de l'examen de parties floues, 40
 - lire des données de référence à valeurs multiples de chacune des couleurs à partir d'un papier imprimé, les données de référence à valeurs multiples étant converties en données monochromes de référence en utilisant les seuils (a, b) de la densité tachée la plus basse et de la densité de flou la plus haute, de sorte que des images de référence monochromes puissent être mémorisées dans une mémoire (24) à partir des données de référence monochromes, 45
 - lire des données d'examen à valeurs multiples de chacune des couleurs à partir d'un papier imprimé, qui est avancé lors de l'examen, les données d'examen à valeurs multiples étant converties en données d'examen monochromes en utilisant les seuils (a, b) de la densité tachée la plus basse et de la densité de flou la plus haute, de sorte que les images monochromes d'examen puissent être mémorisées dans la mémoire (24) à partir des données monochromes d'examen, 50
 - comparer les images d'examen monochromes aux images de référence monochromes en vue de la recherche de parties tachées et de parties floues, 55
 - prédéterminer une surface en vue d'une décision relative à des parties tachées ou à des parties floues,
 - reconnaître si les images monochromes d'examen comprennent ou non des parties ne concordant pas avec les images de référence monochromes, à l'endroit où les parties sont positionnées et quelles surfaces ont les parties, et déterminer ou prendre une décision sur des parties tachées ou des parties floues lorsque les parties ont des surfaces dépassant les surfaces pour une décision de parties tachées ou de parties floues,
 - prédéterminer une limite (c) de moins ou de manque de densité différentielle indépendamment du seuil (a) de la densité tachée plus basse en vue de la recherche d'une insuffisance de densité imprimée à chaque pixel,
 - prédéterminer une limite (d) de plus ou de supplément de densité différentielle indépendamment du seuil (b) de la densité de flou la plus haute en vue d'une recherche d'un excès de densité imprimée à chaque pixel,
 - comparer les données d'examen à valeurs multiples aux données de référence à valeurs multiples à chaque pixel en vue de la reconnaissance d'une différence entre les données de référence à valeurs multiples et les données d'examen à valeurs multiples,
 - prédéterminer une surface en vue d'une décision relative à une insuffisance ou un excès de densité imprimée,
 - décider d'une insuffisance ou d'un excès de densité imprimée lorsque la différence dépasse la limite (c, d) de moins de densité différentielle ou de plus de densité différentielle par des parties ayant des surfaces qui dépassent les surfaces pour la décision d'une insuffisance ou d'un excès de densité imprimée, et exécuter la recherche et la détermination de parties tachées et de parties floues ainsi que la recherche et la détermination d'une insuffisance et d'un excès de densité imprimée simultanément.
2. Procédé selon la revendication 1, dans lequel l'étape de comparaison comprend l'étape consistant à séparer les images de référence monochromes et les images d'examen monochromes en parties pour comparer les images d'examen monochromes aux

images de référence monochromes au niveau de chaque partie.

3. Procédé selon la revendication 1 ou 2, comprenant en outre l'étape consistant à générer une alarme relative aux parties tachées ou aux parties floues lorsque l'on découvre les parties tachées ou les parties floues. 5
4. Procédé selon l'une des revendications 1 à 3, comprenant en outre l'étape consistant à détecter les variations de positions du papier imprimé à chaque page lorsque le papier imprimé est avancé, afin de compenser les images monochromes mémorisées dans la mémoire (24) pour les variations de positions. 10 15
5. Procédé selon l'une des revendications 1 à 4, comprenant en outre l'étape consistant à générer une alarme d'insuffisance ou d'excès de densité imprimée lorsque l'on découvre l'insuffisance ou l'excès de densité imprimée. 20
